PRODUCTION OF FISH

Fish Pond design and construction

A typical earthen fish pond should be 300m\(^2\). The main physical factors to consider are the land area, water supply and the soil water retention capacity.

Land area

The projected land for fish pond construction should be relatively level. Steeply sloped land is not suitable for building ponds. A slope of about 1% is ideal. A farmer should determine an area large enough for the present plans any future expansion. Such an area should not be prone to flooding. The selected area should not be subject to pollution in runoff from adjacent land. If possible, the land must be slightly lower than the water source, so that the ponds can be filled by gravity rather than by pumping.

Water supply

The most common sources of water used for aquaculture are surface waters (streams, springs, lakes) and groundwater (wells, aquifers). Wells and springs are generally preferred for their consistently high quality water. The quantity and quality of water should be adequate to support production. A good water source will be relatively free of silt, aquatic insects, potential predators, and toxic substances, and it will have high concentration of dissolved oxygen. Warm water species like tilapia can tolerate water with lower dissolved oxygen levels, so tilapia culture is often done in static water, that is, without water flowing through the ponds. For earthen ponds, the water source should be able to provide at least 1 m\(^3\) of water (1000 liters) per minute for each hectare of ponds that will be built. If the selected site has relatively poor soils (i.e., soils containing too much sand) the source should be able to provide two to three times more water (2-3 m\(^3\) per minute per hectare).

Soil

Land should be comprised of good quality soil, with little or no gravel or rocks either on the surface or mixed in. Farmers should consider importing clay soil for compacting in the fish pond bottom, sides and core trench to minimize seepage. Soil that will be used to build the dykes must contain at least 20% clay so the finished pond will hold water throughout the growing period.
Some soil with higher clay content—preferably between 30 and 40%—should be available nearby. It will be used to pack the core trenches in the dykes.

In absence of good soils, farmers may consider using dam liners or concrete during fish ponds construction.

**Pond design and layout**

**General considerations**

- Depends on the type of soil present and the intended culture practices.

- The water source must be able to keep the pond full throughout the culture period.

  - Relatively shallow ponds are productive, but the shallow end should be at least 0.5 m deep to avoid invasion by weeds.
  - It is always desirable to place screens on pond inlets and outlets to keep out predators, insects, and unwanted fish, and to retain the cultured fish.

- Every pond should be drainable.

- Every pond should have an independent controlled inlet and outlet.
• Excavation of a core trench should be done where soils are less suitable.

• Perimeter and feeder roads are required to provide for movement of machines during construction and at harvest.

• If you plan to drive on the dykes, build them at least 3 meters wide on top, and wider at the base.

• Soil used to build dykes should always be compacted in layers.

Specific design considerations

1. Water sources used for fishponds

Water sources can be spring water, seepage water, rainwater or run-off, tidewater (marine ponds), water from bore holes (wells), or water pumped or diverted from a river, lake, or reservoir.

Quantity of water needed

Make a decision on the type of fish to be cultured and the size of ponds, so as to determine the amount of water required.

Consider the climatic condition of the area, rainfall pattern, and nature of the soil when calculating quantity of water.

A general rule is that pond water inflow and outflow should equal the pond volume over the period of a month. If inflow is too low, water quality may suffer from oxygen depletion and/or the accumulation of toxicants. However, if the inflow is too high, large amounts of beneficial algae may be flushed from the pond.

As a rule of thumb, ponds should fill up in less than a week. For small ponds, e.g., ponds smaller than 200 m2, 1-inch pipe is recommended. A 400-m2 pond needs a 2-inch pipe, while a pond larger than 4000 m2 will require a 4-inch pipe (see Table 2.1-1).
Estimate the amount of water available from a specific source,

**Steps to pond Construction**

1. Survey the land

2. Clear all vegetation from the site

3. Remove the topsoil from the site

4. Determine pond, drain pipe, and supply canal elevations

5. Peg out the pond, including core trenches, dyke tops, and dyke toes

6. Dig core trenches and pack them with good soil

7. Excavate the pond area

8. Build the dykes

9. Install the drainage system

10. Install the water supply system

**Building your pond**

1. Surveying the land

Clear the land to get line of sight.

Select a reference point for the survey. The standard reference point (—bench markl) is sea level (0 m above sea level). However, in pond construction we use a Temporary Bench Mark (TBM) to help determine elevations and establish slopes. If there is an existing pond use it as the reference point to get the heights of your dykes. If there are no existing ponds, use a fixed point on an inlet or outlet canal as the TBM.
• Start measuring elevations from the supply canal using a level and twine. Determine slope from dyke top to pond bottom for both Vertical and horizontal dimensions. This helps in understanding how water will flow from the pond to the drain or back to the river.

Raise elevation into canals by blocking with timber or sand bags.

• Survey across water bodies using objects such as bamboo, pipes, etc.

2. Clearing vegetation
Vegetation should not be included in the soil used to construct the pond dykes, so should be removed from the site prior to beginning to excavate and move soil.

3. Removing topsoil from the site
Topsoil is not good material to use for dyke construction, so it should be removed prior to excavating the pond.
Topsoil can be set aside and spread over the dykes after construction is complete, or it can be moved for use elsewhere on your farm.

4. Determining pond, drain pipe, and supply canal elevations
• Determine topography (layout) of the land first.
Remember that the elevations of the pond inlet and the outlet to the drain canal determine the elevation at which the pond drain can be placed. Hence the difference in the elevations of the inlet and the outlet determines how deep your pond can be.
• Remember to allow for the freeboard.
• Canal slopes generally range from 0.25% to 1%.
• Cross check your levels to correspond with the TBM so as not to lose dyke height.
• You can also check your pond diagonally, widthwise, and lengthwise.

5. Pegging out the dykes and core trenches
• Decide on the size of the pond and peg the pond area.
• Decide on the dyke slope and width.
• Place pegs at the inner toes, including the four bottom corners. The —toel is the point where the
dyke slope meets the pond bottom. To do this, multiply the desired slope of the dyke by the
desired pond depth. For example, at the deep end, the inner toes will be 80 cm x 2 = 160 cm, while at the shallow end the inner toes will be pegged at 75 cm x 2 = 150 cm

6. Constructing cores
• If you suspect the dyke or pond bottom soil to be highly permeable, dig a core trench under the
dykes around the pond. Pack the core trenches with impermeable clay.

7. Excavating the pond area
• Make a decision on pond depth and calculate the dig/fill heights
• Begin excavating the pond bottom.
• Plan where you take soil from and where you take it to.
• A two-person stretcher works better in black cotton soil than a wheelbarrow.

8. Constructing the dykes (levees)
• The most important component of a pond is its walls (also referred to as the —dykes,‖—levees‖ or —embankments‖).
• Use soil excavated from the pond area to construct the dykes.
• Construct the dykes gradually, in layers about 20 cm thick at a time.
• Compact each layer before the next layer is put down.

9. Installing the drainage system
• Install the drain after the dyke has been raised at least above the original ground level.
• Cut a trench for the drain pipe across the dyke at the selected point in the deep end.
• The top of the drain pipe should be below the deepest part of the pond.
• Lay the pipe at the proper slope through the dyke; slope should be not less than 1%.
  • Install at least one —anti-seep collar along the drain pipe (or small ponds, a PVC pipe
    fitted with a • gate valve would be more suitable `than a monk with timber boards.
  • Place a screen at the outflow to keep out predators and unwanted fish, and to retain the
cultured fish

A prototype measuring a total of 300 m² have been used by Kenya Government as a blue print in
all constituencies. The general features of the pond looks as shown in the figures 1, 2, 3, 4 and 5
below

Figure 3: Width wise section of the pond at the shallow end showing the various measurements

Figure 4: Width wise section of the pond at the deep end showing the various measurements

Figure 5: Plan view showing the pegging positions for a 300 m$^2$ pond
STOCKING THE PONDS

Hatcheries are used to produce fry or fingerlings for stocking fish ponds. A hatchery can also be used as a breeding Centre for genetic improvement of fish stock. Many catfish and tilapia farmers find that an adequate supply of fingerlings is not always available. The demand for fingerlings exists, and a well-managed hatchery can be a lucrative business. Select quality brood stock to improve fish production on your farm.

- Choose pure quality stocks and do not allow them to crossbreed with other strains.
- If buying your fish stocks, buy only from reliable and established sources.
- Use brood fish that are mature but not too old; for catfish and tilapia they should be at least one year old but not more than three years old (> 100 g for tilapia and between 0.5 and 1.0 kg for catfish).

Transferring catfish fry to nursery ponds

- After approximately 14 days in hatchery tanks, the fry can be transferred to ponds.
- Ponds should be well prepared to receive the fry. This includes proper pond bottom drying between crops, liming when needed, and proper fertilization to develop abundant supplies of natural foods for the fry to be stocked.
- Where possible, use hapas in ponds to further protect your fry.

HARVESTING OF FISH

The harvest:

Most earthen pond harvesting is done with a seine net.

- Seine early in the morning, while the weather is still cool.
- Begin seining in the shallow end of the pond and work towards the deep end.
- Work carefully, disturbing the pond bottom as little as possible.
- If possible, finish the seine haul near a water source in the deep end.
- Loosen the seine somewhat to avoid crowding the fish too much during handling.
- Long, forked sticks can be used to hold up the top of the seine.
- If possible, spray a stream of fresh water over the fish while they are being held and handled.
- Gradually lower the water as you near completion of the harvest.
- Use a dipnet to move fish from the seine to buckets on the pond bank.
• Use cast nets, lift nets, hoop nets, or gill nets for harvesting if ponds are too deep or are not drainable, or if you do not have a seine net.

Figure 4.6-2. Harvesting fish with a seine net.

Figure 4.6-3. Using poles to hold up a seine in a pond.

Moving on

A bucket can be used to provide fresh water for fish being harvested.

Fish can be marketed dead or alive. Always handle live fish with care, stressing them as little as possible.

• Keep the fish in fresh water at all times.
• Move fish into less-confined holding tanks as soon as possible
• Transport them to the market as soon after harvest as possible.
• If possible, provide aeration for live fish during transportation
